

Project overview

The company I am currently working for only hold the intellectual properties. However, this application at this current stage was built in my free time and not on company time, therefore I hold all rights to the code and assets of this project and was only to be used for my own research and development to put together an idea that I had of what the project would look like.

This project was to be used to configure a race for Australian Trotting. I would have liked to develop this application more to allow the player to configure the race further, this application is currently in the proposal phase.

What I am allowing the player to do:

- Set the amount of laps
- The distance of the track
- The amount of racers
- Drag and drop racers for the player to race with/against

There would be an option to load in to a pre-configured race by another user or use a default race.

The player would also have the option to choose more than one track. There would be a feature I would like to have created where I look within the C: drive and look to see if there were anymore applications and if there were, I would load them in dynamically.

To run this application

- Please create a folder on the C: drive called "TrotApplication".
 - In the "TrotApplication" folder please create another folder called "System"
 - In the "System" folder please create another folder called "UserSettings".
 - The application will then create the xml files needed.

If for security reasons you do not feel safe to run this application, I completely understand I would not be running code on a machine from a developer I did not trust.

I have commented the code if you would like to just see how the application works from behind the scenes.

Enjoy.
